Abstract: Schweizer–Sklar (SS) operation can make information aggregation more flexible, and the Muirhead mean (MM) operator can take into account the correlation between inputs by a variable parameter. Because traditional MM is only available for real numbers and single-valued neutrosophic set (SVNS) can better express incomplete and uncertain information in decision systems, in this paper, we applied MM operators to single-valued neutrosophic sets (SVNSs) and presented two new MM aggregation operators with the SS operation, i.e., a single-valued neutrosophic SS Muirhead mean (SVNSSMM) operator and a weighted single-valued neutrosophic SS MM (WSVNSSMM) operator. We listed some properties of them and some particular cases about various parameter values. We also proposed the multi-criteria decision-making method based on the WSVNSSMM operator in SVNS. At last, we illustrated the feasibility of this method using a numerical example of company investment.

Keywords: Schweizer–Sklar operations; single-valued neutrosophic set; Muirhead mean operator; MCDM

1. Introduction

Since Zadeh [1] established fuzzy sets (FS), they have developed quickly. However, the inadequacy of FS is obvious because a FS only has a membership degree (MD) $T(x)$, and it cannot deal with some complex fuzzy information. Shortly afterward, Atanassov [2–5] further presented the intuitionistic fuzzy set (IFS). Compared with FS, which only has a membership degree which expresses determinacy, IFS considers the indeterminacy and adds the non-membership degree (NMD) $F(x)$. Nevertheless, in practical issues, IFS also has limitations; it cannot handle the information that blurs the borders between truth and falsity. In order to fix this problem, Atanassov [5] and Gargov [3] extended the MD and NMD to interval numbers and proposed the interval-valued IFS (IVIFS). In addition, Turksen [6] also proposed interval-valued fuzzy sets (IVFS), which also used the MD and NMD to describe determinacy and indeterminacy. However, under some circumstances, the MD and NMD cannot express fuzzy information clearly. Therefore, Smarandache [7] proposed neutrosophic sets (NS) by increasing a hesitation degree $h(x)$. The hesitation degree describes the difference between the MD and NMD. Further, a large number of theories about neutrosophic sets are gradually being put forward. For example, Ye [8] proposed a simple neutrosophic set (SNS), which is a subset of NS. Wang [9] gave the definition of interval NS (INS), which used the standard interval to express the functions of the MD, the hesitation degree, and the NMD. Ye [8] and Wang and Smarandache [10,11] proposed the single-valued neutrosophic set (SVNS), which can solve inaccuracy, incompleteness, and inconsistency problems well.
In fuzzy set theory and application, Archimedean t-norm and t-conorm (ATT) occupy an important position. To promote the classical triangular inequality, Karl Menger [12] proposed the concept of trigonometric function that is the prototype of t-norm and t-conorm. Schweizer and Sklar [13] gave a detailed definition of t-norm and t-conorm, and SS t-norm and t-conorm (SSTT) are one of the forms of t-norm and t-conorm [14–16]. Schweizer-Sklar operation is an instance of ATT, but SS operation contains an alterable parameter; therefore, they are more agile and superior, and can better reflect the property of “logical and” and “logical or”, respectively.

In fuzzy environments, information aggregation operators [17–20] are effective tools to handle multi-criteria decision-making problems, and now they have gained greater attention. In handling multi-criteria decision-making (MCDM) problems, some traditional methods, for instance, TOPSIS (Technique for Order Preference by Similarity to an Ideal Solution) [21] and ELECTRE (Elimination Et Choice Translation Reality) [22], can only give the ranking results, while aggregation operators are able to provide the integrated values of alternatives, and provide the ranking results. In particular, some aggregation operators can take into account the relationship of the aggregated parameter. For instance, Yager [23] gave the power average (PA) operator; this operator aggregates input data and allocates the weighted vector by the support degree between input parameters. Bonferroni [24] proposed the Bonferroni mean (BM) operator and Beliakov [25] presented the Heronian mean (HM) operator, and they can capture the interrelationships between input parameter very well. Then, Yager extended the BM operators to handle different uncertain information such as intuitionistic fuzzy numbers (IFNs) [26], interval-valued IFNs (IVIFNs) [27], and multi-valued neutrosophic numbers [28]. In addition, the HM operator was extended to IFNs [29], IVIFNs [30,31], etc. Furthermore, Yu and Wu [32] explained the difference between the BM and HM. However, the BM and HM operators only consider the relationships between two input parameters. In order to consider interrelationships among multiple input parameters, in 1729, Maclaurin [33] first proposed the Maclaurin symmetric mean (MSM) operator, which has the salient advantage of being able to capture the correlation between arbitrary parameters. After that, a more generalized operator was presented, that is, the Muirhead mean [34] was proposed by Muirhead, which was added an alterable parametric vector \( P \) on the basis of considering interrelationships among multiple input parameters, and some existing operators are its special cases, for instance, arithmetic and geometric mean (GM) operators (not considering the correlations), BM operator, and MSM. When dealing with MCDM problems, some aggregation operators cannot consider the relationship between any input parameters, while MM operator can take into account the correlation between inputs by a variable parameter. Therefore, the MM operator is more superior when deal with MCDM problems.

Multi-criteria decision-making refers to the use of existing decision information, in the case of multi-criteria that are in conflict with each other and cannot coexist, and in which the limited alternatives are ranked or selected in a certain way. Schweizer-Sklar operation uses a variable parameter to make their operations more effective and flexible. In addition, SVNS can handle incomplete, indeterminate, and inconsistent information under fuzzy environments. Therefore, we conducted further research on SS operations for SVNS and applied SS operations to MCDM problems. Furthermore, because the MM operator considers interrelationships among multiple input parameters by the alterable parametric vector, hence combining the MM operator with the SS operation gives some aggregation operators, and it was more meaningful to develop some new means to solve the MCDM problems in the single-valued neutrosophic fuzzy environment. According to this, the purpose and significance of this article are (1) to develop a number of new MM operators by combining MM operators, SS operations, and SVNS; (2) to discuss some meaningful properties and a number of cases of these operators put forward; (3) to deal with an MCDM method for SVNS information more effectively based on the operators put forward; and (4) to demonstrate the viability and superiority of the newly developed method.

In this article, the rest of this paper is as follows. In Section 2, we briefly state the fundamental conceptions of SVNS, SSTT, and MM operators. In Section 3, we develop some single-valued neutrosophic Schweizer–Sklar Muirhead mean operators to explore a number of ideal features and particular cases of the presented operators. In Section 4, we present an MCDM method based on the
developed operators. In Section 5, this paper provides a numerical example of company investment to demonstrate the activeness and feasibility of the presented method, and compare it to other existing methods. In Section 6, we briefly summarize this study.

2. Preliminaries

In the following, we illustrate the notions of SVNS, the operations of Schweizer–Sklar, and the Muirhead mean operator, which will be utilized in the rest of the paper.

2.1. Single-Valued Neutrosophic Set (SVNS)

**Definition 2.1** [20] Let \( X \) be a space of points (objects), with a generic element in \( X \) denoted by \( x \). A neutrosophic set \( A \) in \( X \) is characterized by the degree of membership function \( T_A(x) \), the degree of indeterminacy function \( I_A(x) \), and the degree of non-membership function \( F_A(x) \). If the functions \( T_A(x), I_A(x) \) and \( F_A(x) \) are defined in singleton subintervals or subsets in the real standard \([0,1]\), that is \( T_A(x), I_A(x) \) and \( F_A(x) \) satisfy the condition \( 0 \leq T_A(x) + I_A(x) + F_A(x) \leq 3 \) for any \( x \in X \). Then, a SVNS \( A \) is denoted as follows:

\[
A = \{ <x, T_A(x), I_A(x), F_A(x) > | x \in X \}
\] (1)

For convenience, the ordered triple component \( t = <T_A(x), I_A(x), F_A(x) > \), which is the core of SVNS, can be called a single-valued neutrosophic number (SVNN). What is more, each SVNN can be described as \( a = (T_a, I_a, F_a) \), where \( T_a \in [0,1], I_a \in [0,1], F_a \in [0,1] \), and

**Definition 2.2** [21] For any SVNS \( a = (T_a, I_a, F_a) \), respectively, define the score function \( S(a) \), accuracy function \( A(a) \) and certainty function \( C(a) \) of \( a \) as follows:

\[
S(a) = (T_a + 1 - I_a + 1 - F_a)
\] (2)

\[
A(a) = (T_a - F_a), \text{and}
\]

\[
C(a) = T_a.
\] (4)

**Definition 2.3** [21] Let \( a = (T_a, I_a, F_a) \) and \( b = (T_b, I_b, F_b) \) be any two SVNSs. Define the comparison method as follows:

If \( S(a) > S(b) \), then \( a \succ b \); \n
If \( S(a) = S(b) \) and \( A(a) > A(b) \), then \( a \succ b \); \n
If \( S(a) = S(b), A(a) = A(b) \) and \( C(a) > C(b) \), then \( a \succ b \).

2.2. Muirhead Mean Operator

**Definition 2.4** [22] Let \( \alpha_i (i = 1, 2, 3, ..., n) \) be a set of arbitrary positive real numbers, the parameter vector is \( P = (p_1, p_2, ..., p_s) \in \mathbb{R}^s \). Suppose

\[
MM^P(\alpha_1, \alpha_2, ..., \alpha_s) = \left( \frac{1}{n!} \sum_{\sigma \in S_n} \prod_{j=1}^{n} \alpha_{\sigma(j)}^{p_{\sigma(j)}} \right)^{\frac{1}{\sum_{j=1}^{n} p_j}}
\] (8)
Then, $MM^P$ is called MM operator, the $\sigma(js)(js = 1, 2, ..., n)$ is any permutation of $(1, 2, ..., n)$, and $S_n$ is a set of all permutations of $(1, 2, ..., n)$.

Furthermore, from Equation (8), we can know that

1. If $P=(1,0,...,0)$, the MM reduces to

   $$MM^{(1,0,...,0)}(\alpha_1, \alpha_2, ..., \alpha_n) = \frac{1}{n} \sum_{j=1}^{n} \alpha_j,$$

   which is the arithmetic averaging operator.

2. If $P=(1/1,1/n,...,1/n)$, the MM reduces to

   $$MM^{(1/n,1/n,...,1/n)}(\alpha_1, \alpha_2, ..., \alpha_n) = \prod_{j=1}^{n} \alpha_j^{1/n},$$

   which is the GM operator.

3. If $P=(1/1,1/1,...,1/1)$, the MM reduces to

   $$MM^{(1/1,1/1,...,1/1)}(\alpha_1, \alpha_2, ..., \alpha_n) = \frac{1}{\prod_{i<j}^{n} \alpha_i^{1/n}},$$

   which is the BM operator.

4. If $P=(1,1,...,1,0,0,...,0)$, the MM reduces to

   $$MM^{(1,1,...,1,0,0,...,0)}(\alpha_1, \alpha_2, ..., \alpha_n) = \frac{1}{\prod_{i<j}^{n} \alpha_i^{1/n}},$$

   which is the MSM operator.

From Definition 2.4 and the special cases of the MM operator mentioned above, we know that the advantage of the MM operator is that it can capture the overall interrelationships among the multiple input parameters and it is a generalization of some existing aggregation operators.

2.3. Schweizer–Sklar Operations

Schweizer-Sklar operations contain the SS product and SS sum, they are respectively the particular cases of ATT.

**Definition 2.5** [20] Suppose $A=(a_A,b_A,c_A)$ and $B=(a_B,b_B,c_B)$ are any two SVNSs, then the generalized intersection and union are defined as follows:

$$A \cap_{T,T^*} B = \left\{ y, T_\gamma\left( a_A(y), a_B(y) \right), T_\gamma^*\left( b_A(y), b_B(y) \right), T_\gamma^*\left( c_A(y), c_B(y) \right) \right\} y \in Y \right\} \tag{9}$$

$$A \cup_{T,T^*} B = \left\{ y, T_\gamma\left( a_A(y), a_B(y) \right), T_\gamma^*\left( b_A(y), b_B(y) \right), T_\gamma^*\left( c_A(y), c_B(y) \right) \right\} y \in Y \right\} \tag{10}$$

Where $T_\gamma^*$ expresses a T-norm and $T_\gamma$ expresses a T-conorm.

The definitions of the SS T-norm and T-conorm are described as follows:

$$T_{SS,\gamma}(x,y) = (x^\gamma + y^\gamma - 1)^{1/\gamma} \tag{11}$$

$$T_{SS,\gamma}^*(x,y) = 1 - \left( (1-x)^\gamma + (1-y)^\gamma - 1 \right)^{1/\gamma} \tag{12}$$

Where $\gamma < 0, x, y \in [0,1]$. In addition, when $\gamma = 0$, we have $T_\gamma(x,y) = xy$ and $T_\gamma^*(x,y) = x + y - xy$. They are the algebraic T-norm and algebraic T-conorm.
According to the T-norm \( T_\gamma(x, y) \) and T-conorm \( T_\gamma^*(x, y) \) of SS operations, we define SS operations of SVNSs as follows.

**Definition 2.6** Suppose \( \tilde{a}_1 = (T_A, I_A, F_A) \) and \( \tilde{a}_2 = (T_B, I_B, F_B) \) are any two SVNSs, then present the generalized intersection and generalized union based on SS operations as follows:

\[
\tilde{a}_1 \odot_{T_\gamma} \tilde{a}_2 = \left( T(T_A, T_B), T^*(I_A, I_B), T^*(F_A, F_B) \right) \quad (13)
\]

\[
\tilde{a}_1 \odot_{T_\gamma^*} \tilde{a}_2 = \left( T^*(T_A, T_B), T(I_A, I_B), T(F_A, F_B) \right) \quad (14)
\]

According to Definitions 2.3 and 2.4, the SS operational rules of SVNSs are given as follows (\( \gamma < 0 \)):

\[
\tilde{a}_1 \oplus_{SS} \tilde{a}_2 = \left( 1 - \left[ (1-T_A)^\gamma + (1-T_B)^\gamma - 1 \right]^{\frac{1}{\gamma}}, (I_A^\gamma + I_B^\gamma - 1) \right)^{\frac{1}{\gamma}}, \left( F_A^\gamma + F_B^\gamma - 1 \right) \quad (15)
\]

\[
\tilde{a}_1 \otimes_{SS} \tilde{a}_2 = \left( \left( T^*_A + T^*_B - 1 \right)^{\frac{1}{\gamma}}, 1 - \left[ (1-I_A) + (1-I_B) - 1 \right]^{\frac{1}{\gamma}}, 1 - \left[ (1-F_A) + (1-F_B) - 1 \right]^{\frac{1}{\gamma}} \right) \quad (16)
\]

\[
n\tilde{a}_1 = \left( 1 - \left( n(1-T_A)^\gamma - (n-1) \right)^{\frac{1}{\gamma}}, \left( nI_A^\gamma - (n-1) \right)^{\frac{1}{\gamma}}, \left( nF_A^\gamma - (n-1) \right) \right)^{\frac{1}{\gamma}}, n > 0 \quad (17)
\]

\[
\tilde{a}_1^n = \left( (nT_A^\gamma - (n-1))^\gamma, 1 - \left( n(1-I_A)^\gamma - (n-1) \right)^{\frac{1}{\gamma}}, 1 - \left( n(1-F_A)^\gamma - (n-1) \right)^{\frac{1}{\gamma}} \right), n > 0 \quad (18)
\]

**Theorem 2.1:** Suppose \( \tilde{a}_1 = (T_A, I_A, F_A) \) and \( \tilde{a}_2 = (T_B, I_B, F_B) \) are any two SVNSs, then

\[
(1) \quad \tilde{a}_1 \oplus_{SS} \tilde{a}_2 = \tilde{a}_2 \oplus_{SS} \tilde{a}_1
\]

\[
(2) \quad \tilde{a}_1 \otimes_{SS} \tilde{a}_2 = \tilde{a}_2 \otimes_{SS} \tilde{a}_1
\]

\[
(3) \quad n(\tilde{a}_1 \oplus_{SS} \tilde{a}_2) = n\tilde{a}_1 \oplus_{SS} n\tilde{a}_2, n \geq 0
\]

\[
(4) \quad n\tilde{a}_1 \otimes_{SS} n\tilde{a}_2 = (n_1 + n_2) \tilde{a}_1, n_1, n_2 \geq 0
\]

\[
(5) \quad \tilde{a}_1^n \otimes_{SS} \tilde{a}_2^n = (\tilde{a}_1)^{n_1} \otimes (\tilde{a}_2)^{n_2}, n_1, n_2 \geq 0
\]

\[
(6) \quad \tilde{a}_1^n \otimes_{SS} \tilde{a}_2^n = (\tilde{a}_1 \otimes_{SS} \tilde{a}_2)^n, n \geq 0
\]

**Theorem 2.1** is demonstrated easily.

3. Single-Valued Neutrosophic Schweizer–Sklar Muirhead Mean Aggregation Operators

In the following, we will produce single-valued neutrosophic SS Muirhead mean (SVNSSMM) operators and weighted single-valued neutrosophic SS Muirhead mean (WSVNSSMM) operators and discuss their special cases and some of the properties of the new operators.

3.1. The SVNSSMM Operator

**Definition 3.1** Let \( \alpha_i = (T_i, I_i, F_i) (i = 1, 2, \ldots, n) \) be a set of SVNSs, and \( P = (p_1, p_2, \ldots, p_n) \in R^n \) be a vector of parameters. If

\[
SVNSSMM^P (\alpha_1, \alpha_2, \ldots, \alpha_n) = \left( \frac{1}{n!} \sum_{\sigma \in \Sigma_n} \prod_{j=1}^{n} \alpha_{\sigma(j)}^{p_{\sigma(j)}} \right)^{\frac{1}{\sum_{j=1}^{n} p_j}} \quad (25)
\]
Then we call $SVNSSMM^p$ as the single-valued neutrosophic Schweizer–Sklar MM (SVNSSMM) operator, where $\sigma(j)(j=1,2,\cdots,n)$ is any a permutation of $(1,2,\cdots,n)$, and $S_n$ is the set of all permutations of $(1,2,\cdots,n)$.

Based on the SS operational rules of the SVNSs, we give the result of Definition 3.1 as shown as Theorem 3.1.

**Theorem 3.1** Let $\alpha_i = (T_i, I_i, F_i)(i=1,2,\cdots,n)$ be a collection of SVNSs and $\gamma < 0$, then the result generated by Definition 3.1 can be shown as

$$SVNSSMM^p(\alpha_i, \alpha_2, \ldots, \alpha_n) = \left\{ 1 + \frac{1}{\sum_{j=1}^{n} P_j} \left( \frac{1}{n!} \sum_{\sigma \in S_n} \left[ 1 - \left( \frac{1}{1 - P_j} \right)^{\gamma} \right]^\gamma \right) - 1 \right\}$$

Proof.

By the operational laws of SVNSs based on SS operations, we get

$$\alpha_{\sigma(j)}^p = \left( \sum_{j=1}^{n} P_{T_{\sigma(j)}} - \sum_{j=1}^{n} P_{I_{\sigma(j)}} \right)^\frac{1}{\gamma} , 1 - \left( \sum_{j=1}^{n} P_{F_{\sigma(j)}} - \sum_{j=1}^{n} P_{I_{\sigma(j)}} \right)^\frac{1}{\gamma} , 1 - \left( \sum_{j=1}^{n} P_{I_{\sigma(j)}} - \sum_{j=1}^{n} P_{F_{\sigma(j)}} \right)^\frac{1}{\gamma}$$

and

$$\prod_{j=1}^{n} \alpha_{\sigma(j)}^p = \left( \sum_{j=1}^{n} P_{T_{\sigma(j)}} - \sum_{j=1}^{n} P_{I_{\sigma(j)}} + 1 \right)^\frac{1}{\gamma} , 1 - \left( \sum_{j=1}^{n} P_{F_{\sigma(j)}} - \sum_{j=1}^{n} P_{I_{\sigma(j)}} + 1 \right)^\frac{1}{\gamma} , 1 - \left( \sum_{j=1}^{n} P_{I_{\sigma(j)}} - \sum_{j=1}^{n} P_{F_{\sigma(j)}} + 1 \right)^\frac{1}{\gamma}$$

Then

$$\sum_{\sigma \in S_n} \prod_{j=1}^{n} \alpha_{\sigma(j)}^p = \left\{ 1 - \left( \sum_{\sigma \in S_n} \left[ 1 - \left( \frac{1}{1 - P_j} \right)^{\gamma} \right]^\gamma \right) - 1 \right\}$$
Thus, we are able to obtain

\[
\left\{ \sum_{j=1}^{n} \left( \sum_{j=1}^{n} P_{j} \left( 1 - I_{\alpha_{j}} \right) - \sum_{j=1}^{n} P_{j} + 1 \right)^{\gamma} - 1 \right\}^{\frac{1}{\gamma}} \left\{ \sum_{j=1}^{n} \left( \sum_{j=1}^{n} P_{j} \left( 1 - F_{\alpha_{j}} \right) - \sum_{j=1}^{n} P_{j} + 1 \right)^{\gamma} - 1 \right\}^{\frac{1}{\gamma}}
\]

Further, we are able to obtain

\[
\frac{1}{n!} \sum_{\sigma_{j=1}^{n}} \prod_{j=1}^{n} \alpha_{\sigma_{j}}^{P_{j}} = \left( 1 - \frac{1}{n!} \sum_{\sigma_{j=1}^{n}} \left( 1 - \left( \sum_{j=1}^{n} P_{j} \right)^{\gamma} - \sum_{j=1}^{n} P_{j} + 1 \right)^{\gamma} - 1 \right) \left( 1 - \frac{1}{n!} \sum_{\sigma_{j=1}^{n}} \left( 1 - \left( \sum_{j=1}^{n} P_{j} \right)^{\gamma} - \sum_{j=1}^{n} P_{j} + 1 \right)^{\gamma} - 1 \right)
\]

Therefore

\[
\text{SIMSJM}^{\text{23}}(x, y, z) = \left( 1 - \frac{1}{\sum_{j=1}^{n} P_{j}} \left( 1 - \frac{1}{n!} \sum_{\sigma_{j=1}^{n}} \left( 1 - \left( \sum_{j=1}^{n} P_{j} \right)^{\gamma} - 1 \right) \right) - 2 \right) \frac{1}{\sum_{j=1}^{n} P_{j}}
\]

\[
1 - \frac{1 + \frac{1}{\sum_{j=1}^{n} P_{j}} \left( 1 - \frac{1}{n!} \sum_{\sigma_{j=1}^{n}} \left( 1 - \left( \sum_{j=1}^{n} P_{j} \right)^{\gamma} - 1 \right) \right) - 2 \right) \frac{1}{\sum_{j=1}^{n} P_{j}}
\]

\[
1 - \frac{1 + \frac{1}{\sum_{j=1}^{n} P_{j}} \left( 1 - \frac{1}{n!} \sum_{\sigma_{j=1}^{n}} \left( 1 - \left( \sum_{j=1}^{n} P_{j} \right)^{\gamma} - 1 \right) \right) - 2 \right) \frac{1}{\sum_{j=1}^{n} P_{j}}
\]
1 + \frac{1}{\sum_{j=1}^{n} P_j} \left( 1 - \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{n} P_j \left( T'_{\sigma(j)} - 1 \right) \right)^{\frac{1}{\gamma}} - 2 \right) \right)^{\frac{1}{\gamma}} \left( 1 + \frac{1}{\sum_{j=1}^{n} P_j} \right)

= (0.5401, 0.3966, 0.4420).

**Theorem 3.2 (Monotonicity).** Let \( \alpha_i = (T_i, I_i, F_i) \) and \( \alpha'_i = (T'_i, I'_i, F'_i) \) \((1, 2, \ldots, n)\) be two sets of SVNSs. If \( T_i \geq T'_i, I_i \leq I'_i, F_i \leq F'_i \) for all \( i \), then

\[
SVNSSMM^\rho(\alpha_1, \alpha_2, \ldots, \alpha_n) \geq SVNSSMM^\rho(\alpha'_1, \alpha'_2, \ldots, \alpha'_n)
\]  

**Proof.**

Let \( SVNSSMM^\rho(\alpha_1, \alpha_2, \ldots, \alpha_n) = (T, I, F) \),

\( SVNSSMM^\rho(\alpha'_1, \alpha'_2, \ldots, \alpha'_n) = (T', I', F') \).

Where

\[
T = \left( 1 + \frac{1}{\sum_{j=1}^{n} P_j} \right) \left( 1 - \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{n} P_j \left( T'_{\sigma(j)} - 1 \right) \right)^{\frac{1}{\gamma}} - 2 \right) \right)^{\frac{1}{\gamma}} \left( 1 + \frac{1}{\sum_{j=1}^{n} P_j} \right)
\]

\[
T' = \left( 1 + \frac{1}{\sum_{j=1}^{n} P_j} \right) \left( 1 - \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{n} P_j \left( T'_{\sigma(j)} - 1 \right) \right)^{\frac{1}{\gamma}} - 2 \right) \right)^{\frac{1}{\gamma}} \left( 1 + \frac{1}{\sum_{j=1}^{n} P_j} \right)
\]

and
\[
I = 1 + \frac{1}{\sum_{j=1}^{n} p_j} \left( 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - I_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \right) - \frac{1}{\sum_{j=1}^{n} p_j} \right)^{\frac{1}{\gamma}}
\]

\[
I' = 1 + \frac{1}{\sum_{j=1}^{n} p_j} \left( 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - I'_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \right) - \frac{1}{\sum_{j=1}^{n} p_j} \right)^{\frac{1}{\gamma}}
\]

\[
F = 1 + \frac{1}{\sum_{j=1}^{n} p_j} \left( 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - F_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \right) - \frac{1}{\sum_{j=1}^{n} p_j} \right)^{\frac{1}{\gamma}}
\]

\[
F' = 1 + \frac{1}{\sum_{j=1}^{n} p_j} \left( 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - F'_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \right) - \frac{1}{\sum_{j=1}^{n} p_j} \right)^{\frac{1}{\gamma}}
\]

Since \( T_i \geq T_i' \) and \( \gamma < 0 \) we can get \( T'_{\sigma(j)} \leq T''_{\sigma(j)} \).

\[
\left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T'_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \leq \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T''_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}}
\]

Then

\[
\Rightarrow 1 - \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T'_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \leq 1 - \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T''_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}}
\]

\[
\Rightarrow \left( 1 - \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T'_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \right)^{\gamma} \geq \left( 1 - \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T''_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \right)^{\gamma}
\]

\[
\Rightarrow 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T'_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \leq 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T''_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} - 2
\]

\[
\Rightarrow 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T''_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} \leq 1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left( 1 + \sum_{j=1}^{d-1} p_j \left( (1 - T'_{\sigma(j)})^{\frac{1}{\gamma}} - 1 \right) \right)^{\frac{1}{\gamma}} - 2
\]
\[
\Rightarrow \left[1 - \frac{1}{n} \sum_{j=1}^{n} \left(1 - \left(1 + \sum_{i \neq j} \lambda \left(T_{ij} - 1\right)\right)^{-1}\right)^{-2}\right]^{\frac{n}{\gamma}} \leq \left[1 - \frac{1}{n} \sum_{j=1}^{n} \left(1 + \sum_{i \neq j} \lambda \left(T_{ij} - 1\right)\right)^{-1}\right]^{\frac{n}{\gamma}} - 2\] 

\[
= \left[\frac{1}{\sum_{j=1}^{n} \left(1 + \sum_{i \neq j} \lambda \left(T_{ij} - 1\right)\right)^{-1}}\right]^{\frac{n}{\gamma}} \leq \left[\frac{1}{\sum_{j=1}^{n} \left(1 + \sum_{i \neq j} \lambda \left(T_{ij} - 1\right)\right)^{-1}}\right]^{\frac{n}{\gamma}} - 2\] 

i.e., \( T_j \geq T'_j \).

Similarly, we also have \( I_i \leq I'_i, F_i \leq F'_i \).

Therefore, we can get the following conclusion.

\( SVNSSMM^\rho (\alpha_1, \alpha_2, \ldots, \alpha_n) \geq SVNSSMM^\rho (\alpha'_1, \alpha'_2, \ldots, \alpha'_n) \)

**Theorem 3.3 (Commutativity).** Suppose \( \alpha'_i (i = 1, 2, \ldots, n) \) is any permutation of \( \alpha_j (i = 1, 2, \ldots, n) \). Then

\[
SVNSSMM^\rho (\alpha_1, \alpha_2, \ldots, \alpha_n) = SVNSSMM^\rho (\alpha'_1, \alpha'_2, \ldots, \alpha'_n) \quad (28)
\]

Because this property is clear, so the proof is now omitted.

In the following, we will research several particular forms of the SVNSSMM operator with the different parameters vector \( \lambda \).

1. When \( P = (1, 0, \ldots, 0) \), the SVNSSMM operator will reduce to the single-valued neutrosophic Schweizer–Sklar arithmetic averaging operator.

\[
SVNSSMM^{(1,0,\ldots,0)} (\alpha_1, \alpha_2, \ldots, \alpha_n) = \frac{1}{n} \sum_{j=1}^{n} \alpha_j
\]

\[
= \left[1 - \frac{1}{n} \sum_{j=1}^{n} \left(1 - T_j\right)^{-1} - 2\right]^{\frac{n}{\gamma}} \cdot \left[1 + \frac{1}{n} \sum_{j=1}^{n} \left(I_j - 2\right)\right]^{\frac{n}{\gamma}} \cdot \left[1 + \frac{1}{n} \sum_{j=1}^{n} \left(F_j - 2\right)\right]^{\frac{n}{\gamma}} \quad (29)
\]

2. When \( P = (\lambda, 0, \ldots, 0) \), the SVNSSMM operator will reduce to the single valued neutrosophic Schweizer–Sklar generalized arithmetic averaging operator.

\[
SVNSSMM^{(\lambda,0,\ldots,0)} (\alpha_1, \alpha_2, \ldots, \alpha_n) = \left(\frac{1}{n} \sum_{j=1}^{n} \alpha_j\right)^{1/\lambda}
\]

\[
= \left[\frac{1}{\lambda} \left(1 - \frac{1}{n} \sum_{j=1}^{n} \left(1 - \left(1 + \lambda (T_j - 1)\right)^{-1}\right)^{-2}\right)\right]^{\frac{n}{\gamma}} \cdot \left[1 - \frac{1}{\lambda} \left(1 + \frac{1}{n} \sum_{j=1}^{n} \left(1 + \lambda (1 - I_j)^{-1}\right)^{-2}\right)\right]^{\frac{n}{\gamma}} - 1\] 

\[
1 - \frac{1}{\lambda} \left(1 - \frac{1}{n} \sum_{j=1}^{n} \left(1 - \left(1 + \lambda (1 - I_j)^{-1}\right)^{-1}\right)^{-2}\right)\right]^{\frac{n}{\gamma}} - 1\] 

\[
= \left[\frac{1}{\lambda} \left(1 - \frac{1}{n} \sum_{j=1}^{n} \left(1 - \left(1 + \lambda (T_j - 1)\right)^{-1}\right)^{-2}\right)\right]^{\frac{n}{\gamma}} \cdot \left[1 - \frac{1}{\lambda} \left(1 + \frac{1}{n} \sum_{j=1}^{n} \left(1 + \lambda (1 - I_j)^{-1}\right)^{-2}\right)\right]^{\frac{n}{\gamma}} - 1\] 

\[
= \left[\frac{1}{\lambda} \left(1 - \frac{1}{n} \sum_{j=1}^{n} \left(1 - \left(1 + \lambda (T_j - 1)\right)^{-1}\right)^{-2}\right)\right]^{\frac{n}{\gamma}} \cdot \left[1 - \frac{1}{\lambda} \left(1 + \frac{1}{n} \sum_{j=1}^{n} \left(1 + \lambda (1 - I_j)^{-1}\right)^{-2}\right)\right]^{\frac{n}{\gamma}} - 1\]
\[
1 - \left( 1 + \frac{1}{\lambda} \right) \left( 1 - \left( 1 + \frac{1}{n} \sum_{j=1}^{n} \left( 1 - \left( 1 + \lambda \left( (1 - F_j)^\gamma - 1 \right) \right)^{\gamma} \right)^{\gamma} - 2 \right) \right)^{\gamma} x^{\gamma} \right)
\]

(3) When \( P = (1, 1, 0, 0, \ldots, 0) \), the SVNSSMM operator will reduce to the single-valued neutrosophic Schweizer–Sklar BM operator.

\[
SVNSSMM^{(1,1,0,0,\ldots,0)}(\alpha_1, \alpha_2, \ldots, \alpha_n) = \left( \frac{1}{n(n-1)} \sum_{i,j=1 \atop i \neq j}^{n} \alpha_i \alpha_j \right)^{\gamma} \]

\[
= \left( 1 + \frac{1}{n(n-1)} \sum_{i,j=1 \atop i \neq j}^{n} (1 - (1 - I_i)^\gamma + (1 - I_j)^\gamma - 1)^{\gamma} \right)^{\gamma} x^{\gamma} \right)
\]

(31)

(4) When \( P = (1, 1, \ldots, 1, 0, 0, \ldots, 0) \), the SVNSSMM operator will reduce to the single-valued neutrosophic Schweizer–Sklar Maclaurin symmetric mean (MSM) operator.

\[
SVNSSMM^{(1,1,\ldots,1,0,0,\ldots,0)}(\alpha_1, \alpha_2, \ldots, \alpha_n) = \left( \frac{1}{C_n^k} \sum_{i_1 \leq \ldots \leq i_k \leq n} \alpha_{i_1} \otimes \alpha_{i_2} \otimes \ldots \otimes \alpha_{i_k} \right)^{\gamma} \]

\[
= \left( 1 + \frac{1}{k} \left( \left( 1 + \frac{1}{C_n^k} \sum_{i_1 \leq \ldots \leq i_k \leq n} \left( \left( \sum_{j=1}^{k} T_{i_j}^\gamma - 1 \right)^{\gamma} - 2 \right) \right)^{\gamma} - 1 \right) \right)^{\gamma} x^{\gamma} \right)
\]

(32)

\[
1 - \left( 1 + \frac{1}{k} \left( \left( \frac{1}{C_n^k} \sum_{i_1 \leq \ldots \leq i_k \leq n} \left( \left( \sum_{j=1}^{k} (1 - I_{i_j})^\gamma - 1 \right)^{\gamma} - 2 \right) \right)^{\gamma} - 1 \right) \right)^{\gamma} x^{\gamma} \right)
\]
When \( P = (1,1, \ldots, 1) \), the SVNSSMM operator will reduce to the single-valued neutrosophic Schweizer–Sklar geometric averaging operator.

\[
SVNSSMM^{(1,1, \ldots, 1)}\left(\alpha_1, \alpha_2, \ldots, \alpha_n\right) = \left(\prod_{j=1}^{n} \alpha_j\right)^{1/n}
\]

(33) \[\begin{align*}
1 - \left(1 + \frac{1}{k} \left(1 - \left(1 + \frac{1}{C_n^k} \sum_{j_1 < \cdots < j_k \leq n} \left(1 - \left(1 - F_{j_1} \right)^{\gamma} \right)^{-1} \right)^{\frac{1}{\gamma}}\right)^{-2}\right) \leq \frac{1}{k} \leq 1
\end{align*}\]
Theorem 3.7

\[
W_{SVNSSMM}^p(\alpha, \alpha_2, \ldots, \alpha_n) = \left(1 + \frac{1}{\sum_{j=1}^n P_j} \left[1 - \left(1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left(1 - \sum_{j=1}^n P_j \omega_{\sigma(j)} \left(T_{\sigma(j)} - 1\right)^{\gamma}\right)^{\gamma}\right) - 1\right] - 1\right) \gamma^{\gamma^2} - \frac{1}{\sum_{j=1}^n P_j},
\]

Theorem 3.6

\[
W_{SVNSSMM}^p(\alpha, \alpha_2, \ldots, \alpha_n) \geq W_{SVNSSMM}^p(\alpha_1, \alpha_2, \ldots, \alpha_n)
\]

Theorem 3.5 (Monotonicity). Let \( \alpha_i = (T_i, I_i, F_i) \) and \( \alpha'_i = (T'_i, I'_i, F'_i) \) \((1, 2, \ldots, n)\) be two sets of SVNSs. If \( T_i \geq T'_i, I_i \leq I'_i, F_i \leq F'_i \) for all \( i \), then

The proofs of Theorem 3.5 and 3.6 are the same as the proofs of monotonicity and commutativity of the SVNSSMM operator, so it will not be repeated here.

Theorem 3.7 The SVNSSMM operator is a particular case of the WSVNSSMM operator.

Proof.

When \( \omega = \left(\frac{1}{n}, \frac{1}{n}, \ldots, \frac{1}{n}\right) \),

\[
W_{SVNSSMM}^p(\alpha, \alpha_2, \ldots, \alpha_n) = \left(1 + \frac{1}{\sum_{j=1}^n P_j} \left[1 - \left(1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left(1 - \sum_{j=1}^n P_j \omega_{\sigma(j)} \left(T_{\sigma(j)} - 1\right)^{\gamma}\right)^{\gamma}\right) - 1\right] - 1\right) \gamma^{\gamma^2} - \frac{1}{\sum_{j=1}^n P_j},
\]

then

\[
1 - \left(1 + \frac{1}{\sum_{j=1}^n P_j} \left[1 - \left(1 + \frac{1}{n!} \sum_{\sigma \in S_n} \left(1 - \sum_{j=1}^n P_j \omega_{\sigma(j)} \left(T_{\sigma(j)} - 1\right)^{\gamma}\right)^{\gamma}\right) - 1\right] - 1\right) \gamma^{\gamma^2} - \frac{1}{\sum_{j=1}^n P_j},
\]
\[
1 - \left(1 + \frac{1}{\sum_{j=1}^{n} P_j} \left[1 - \frac{1}{n} \sum_{\sigma, s} \left(1 + \sum_{j=1}^{n} P_j \cdot m \sigma_{\sigma(j)} \left(\left(1 - F_{\sigma(j)}\right)^{\gamma} - 1\right)^{\gamma} - 2\right) \right] \right)^{\frac{1}{\gamma}} = SVNSSM_{P}^{\gamma} (\alpha_1, \alpha_2, \ldots, \alpha_n).
\]
4. MCDM Method Based on WSVNSSMM Operator

In the next, we are going to put forward a novel MCDM method based on the WSVNSSMM operator as described below.

Assume \( A=\{A_1, A_2, \ldots, A_M\} \) is a collection of alternatives, and \( C=\{C_1, C_2, \ldots, C_n\} \) is a collection of \( n \) criteria. Suppose the weight vector of the criterion is \( \omega=(\omega_1, \omega_2, \ldots, \omega_n)^T \) and satisfies \( \omega_j \in [0,1] \) and \( \sum_{j=1}^{n} \omega_j = 1 \), and \( \omega_j \) denotes the importance of the criteria \( c_j \). The performance degree of alternative \( a_i \) in criteria \( c_j \) is measured by SVNSs and the decision matrix is \( R=(r_{ij})_{m \times n} \), where \( r_{ij}=(T_{ij}, I_{ij}, F_{ij}) \). After that, ranking its alternatives is the main purpose. Finally, we give the detailed decision-making steps.

Step 1: Normalizing the criterion values.

In the real decision, there are two types of criteria: one is the benefit and the other is the cost type. To hold consistency of this type, the first step is to convert the criteria type to a consistent type. In general, the cost type should be changed to the benefit type. The formula is as follows:

If \( c_j \) is the cost type, then

\[
  r_{ij} = (F_{ij}, 1-I_{ij}, T_{ij}), \text{ else } r_{ij} = (T_{ij}, I_{ij}, F_{ij})
\]

Step 2: Aggregating all criterion values for each alternative.

We would utilize Definition 3.2 to obtain the comprehensive value shown as follows:

\[
  Z_i = WSVNSSMM(r_{i1}, r_{i2}, \ldots, r_{in})
\]

Step 3: Calculate the score values of \( r_i (i = 1, 2, \ldots, n) \) by Definition 2.2.

After that, when two score values of them are equal, we would calculate the accuracy values and certainty function.

Step 4: Rank all the alternatives.

Based on Step 3 and Definition 2.3, we will obtain the order of alternatives.

5. Numerical Example

In this subsection, we refer to an example of MCDM to prove the feasibility and validity of the presented method.

We refer to the decision-making problem in Reference [8]. There is an investment company, which intends to choose the best investment in the possible alternatives. There are four possible options for the investment company to choose from: (1) a car company \( A_1 \); (2) a food company \( A_2 \); (3) a computer company \( A_3 \); (4) an arms company \( A_4 \). The investment company shall consider the following three evaluation indexes to make choices: (1) the risk analysis \( C_1 \); (2) the growth analysis \( C_2 \); and (3) the environmental influence analysis. Among \( C_1 \) and \( C_2 \) are the benefit criteria and \( C_3 \) is the cost criterion. The weight vector of the criteria is \( \omega=(0.35, 0.25, 0.4)^T \). The four possible alternatives are evaluated with respect to the above three criteria by the form of SVNSNs, and single-valued neutrosophic decision matrix \( D \) is constructed as listed in Table 1.
Table 1. Decision Matrix D.

<table>
<thead>
<tr>
<th>Options</th>
<th>Attributes</th>
<th>C₁</th>
<th>C₂</th>
<th>C₃</th>
</tr>
</thead>
<tbody>
<tr>
<td>A₁</td>
<td></td>
<td>(0.4,0.2,0.3)</td>
<td>(0.4,0.2,0.3)</td>
<td>(0.2,0.2,0.5)</td>
</tr>
<tr>
<td>A₂</td>
<td></td>
<td>(0.6,0.1,0.2)</td>
<td>(0.6,0.1,0.2)</td>
<td>(0.5,0.2,0.2)</td>
</tr>
<tr>
<td>A₃</td>
<td></td>
<td>(0.3,0.2,0.3)</td>
<td>(0.5,0.2,0.3)</td>
<td>(0.5,0.3,0.2)</td>
</tr>
<tr>
<td>A₄</td>
<td></td>
<td>(0.7,0.0,0.1)</td>
<td>(0.6,0.1,0.2)</td>
<td>(0.4,0.3,0.2)</td>
</tr>
</tbody>
</table>

5.1. Rank the Alternatives by the WSVNSSMM Operator

The step is described as follows:

Step 1: Normalizing the criterion values.

In this case, C₁ and C₂ are benefit types, and C₃ is a cost type, so we set up the decision matrix as shown in Table 2.

Table 2. Normalize the Decision Matrix D.

<table>
<thead>
<tr>
<th>Options</th>
<th>Attributes</th>
<th>C₁</th>
<th>C₂</th>
<th>C₃</th>
</tr>
</thead>
<tbody>
<tr>
<td>A₁</td>
<td></td>
<td>(0.4,0.2,0.3)</td>
<td>(0.4,0.2,0.3)</td>
<td>(0.2,0.2,0.5)</td>
</tr>
<tr>
<td>A₂</td>
<td></td>
<td>(0.6,0.1,0.2)</td>
<td>(0.6,0.1,0.2)</td>
<td>(0.5,0.2,0.2)</td>
</tr>
<tr>
<td>A₃</td>
<td></td>
<td>(0.3,0.2,0.3)</td>
<td>(0.5,0.2,0.3)</td>
<td>(0.5,0.3,0.2)</td>
</tr>
<tr>
<td>A₄</td>
<td></td>
<td>(0.7,0.0,0.1)</td>
<td>(0.6,0.1,0.2)</td>
<td>(0.4,0.3,0.2)</td>
</tr>
</tbody>
</table>

Step 2: Aggregating all criterion values for each alternative. Utilize Definition 3.2 to obtain the comprehensive value Z and suppose P = (1,1,1) and γ = -2 that have

Z₁ = (0.4878,0.1864,0.3361), Z₂ = (0.6379,0.1384,0.1864),
Z₃ = (0.5480,0.2227,0.2380), Z₄ = (0.6097,0.1667,0.1600).

Step 3: Calculate the score function S(z₁)(i = 1,2,3,4) of the value z₁(i = 1,2,3,4).

S(z₁) = 1.9653, S(z₂) = 2.3131, S(z₃) = 2.0872, S(z₄) = 2.2831.

Step 4: Ranking all the alternatives.

Based on the score functions S(z₁)(i = 1,2,3,4), we will obtain the order of alternatives \{A₁,A₂,A₃,A₄\} is A₂ > A₁ > A₄ > A₃. Obviously, the best alternative is A₂.

5.2. The Influence of the Parameters Vector on Decision-Making Result of This Example

To verify the impact of the parameters vectors γ and P on the decision-making of the instance, we select diverse parameters vectors γ and P, and give the sorting results of the alternatives. We can see the results in Tables 3–5.

When γ = -2, parameter vector P takes different values, the sorting results of alternatives are given in Table 3.
### Table 3. Comparisons of different values of $P$ when $\gamma = -2$.

<table>
<thead>
<tr>
<th>Parameters Vector $P$</th>
<th>The Score Function $S(z_i)$</th>
<th>Ranking Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>$(1, 0, 0)$</td>
<td>$S(z_1) = 1.9417, S(z_2) = 2.3175$  ( S(z_3) = 2.0575, S(z_4) = 2.3708 )</td>
<td>$A_1 &gt; A_2 &gt; A_3 &gt; A_4$</td>
</tr>
<tr>
<td>$(1, 1, 0)$</td>
<td>$S(z_1) = 1.9400, S(z_2) = 2.3046$  ( S(z_3) = 2.0574, S(z_4) = 2.3904 )</td>
<td>$A_1 &gt; A_2 &gt; A_3 &gt; A_4$</td>
</tr>
<tr>
<td>$(1, 1, 1)$</td>
<td>$S(z_1) = 1.9653, S(z_2) = 2.3131$  ( S(z_3) = 2.0872, S(z_4) = 2.2831 )</td>
<td>$A_2 &gt; A_1 &gt; A_3 &gt; A_4$</td>
</tr>
<tr>
<td>$(0.25, 0.25, 0.25)$</td>
<td>$S(z_1) = 1.9653, S(z_2) = 2.3131$  ( S(z_3) = 2.0872, S(z_4) = 2.2831 )</td>
<td>$A_2 &gt; A_1 &gt; A_3 &gt; A_4$</td>
</tr>
<tr>
<td>$(2, 0, 0)$</td>
<td>$S(z_1) = 2.0105, S(z_2) = 2.3463$  ( S(z_3) = 2.1100, S(z_4) = 2.3843 )</td>
<td>$A_2 &gt; A_1 &gt; A_3 &gt; A_4$</td>
</tr>
<tr>
<td>$(3, 0, 0)$</td>
<td>$S(z_1) = 2.0696, S(z_2) = 2.3742$  ( S(z_3) = 2.1578, S(z_4) = 2.4004 )</td>
<td>$A_1 &gt; A_3 &gt; A_2 &gt; A_4$</td>
</tr>
</tbody>
</table>

When $\gamma = -5$, parameter vector $P$ takes different values, the sorting results of alternatives are given in Table 4.

### Table 4. Comparisons of different values of $P$ when $\gamma = -5$.

</tbody>
</table>

As is shown in Tables 3–5, when the parameter vector $P$ are the same and $\gamma$ are changeable, the scoring functions are changes, but the ranking results are still the same. Usually, the ranking result is the same when $\gamma = -200$ by verification, the different decision-makers can choose diverse parameters values $\gamma$ according to their preferences, so we might assume $\gamma = -2$ here. What is more, if the parameter value $\gamma$ are fixed and parameter values $P$ are different, we can get different ranking results. For example, When $P = (1, 1, 1)$ considers interrelationships among all input parameters, the sorting order is $A_2 \succ A_4 \succ A_3 \succ A_1$, so the best option is $A_2$; nevertheless, when $P = (1, 0, 0)$ and $P = (1, 1, 0)$, the sorting result is $A_4 \succ A_2 \succ A_3 \succ A_1$, so the best option is $A_4$. In addition, on the basis of the above results, we can know that for the WSVNSSMM operator the score function value decreases as the correlations of criteria increases, in other words, the more 0 in the parameters vector $P$, the larger the value of the score functions. Hence, the decision-makers are able to set diverse parameters vector $\gamma$ and $P$ by means of different risk preferences.

5.3. Comparing with the Other Methods

So as to demonstrate the validity of the method presented in this thesis, we can use the existing methods including the cosine similarity measure proposed by Ye [8], the single-valued neutrosophic weighted Bonferroni mean (WSVNBM) operator extended from the normal neutrosophic weighted Bonferroni mean (NNWBM) [37] operator, the weighted correlation coefficient proposed by Ye [38] to illustrate this numerical example. The sorting results of these methods are given from Tables 6 and 7.

According to Table 6, we can see that the best alternatives $A_2$ and the ranking results obtained by these methods are the same. This result indicates the validity and viability of the new method put forward in this thesis. After that, we further analyzed, that for when the parameter vectors were $P = (1, 0, 0)$ or $P = (2, 0, 0)$, whether the WSVNSSMM would reduce to the weighted single-valued neutrosophic Schweizer–Sklar arithmetic averaging operator. That is to say, when $P = (1, 0, 0)$ is similar to the method based on cosine similarity measurement proposed by Ye [8], we can think the input parameters are independent and the interrelationship between input...
parameters is not taken into account. When \( P = (1, 1, 0) \), the WSVNSSMM will reduce to the weighted single-valued neutrosophic SS BM operator, which can take the interrelationship of two input parameters into account and its sorting result is the same as that of WSVNBM. In addition, from Table 7, we can see Ye [38] also put forward a method based on the weighted correlation coefficient to get a sorting result which was \( A_2 > A_4 > A_3 > A_1 \). When \( P = (1, 1, 1) \), the sorting result was \( A_2 > A_1 > A_2 > A_3 \), which shows that the best alternative is not only \( A_4 \), but \( A_2 \) is also possible, and the WSVNSSMM method developed in this thesis is more comprehensive. Therefore, the presented methods in this thesis are a generalization of many existing methods.

In real decision-making environments, we should take into account two parameters, multiple parameters, or not consider parameters based on the preference of the decision-makers, and the presented methods in this paper can capture all of the above situations by changing parameter \( P \).

### Table 6. Comparison of the different methods.

<td>( A_4 &gt; A_1 &gt; A_3 &gt; A_1 )</td>
</tr>
</tbody>
</table>

In short, from the above comparative analysis, we are aware that the methods in this thesis are better, more advanced, and more effective based on the WSVNSSMM operator. Hence, the methods we presented are more advantageous in dealing with such decision-making problems.

### 6. Conclusions

The MCDM problems based on SVNS information is widely applied in various fields. In this paper, we used the Schweizer–Sklar operation rule and we considered the MM operator’s own the remarkable feature, particularly the correlation between attributes through parameter vector \( P \). In the single-valued neutrosophic environment, we combine the MM operator with the SS operation rule, then presented two new MM aggregation operators, respectively, the single-valued neutrosophic Schweizer–Sklar Muirhead mean (SVNSSMM) operator and the weighted single-valued neutrosophic Schweizer–Sklar Muirhead (WSVNSSMM) operator. After that, we explained the ideal feature and some particular cases of the new operators in detail. Lastly, the methods presented in this paper were compared with other methods by numerical example to verify the viability of these methods. In the future, using the WSVNSSMM operator can help us to settle more complex MCDM problems. Moreover, we would further study other aggregation operators to handle MCDM problems.
Author Contributions: In this article, a short paragraph specifying authors’ individual contributions must be provided. Y.G. conceived and designed the experiments; H.Z. and F.W. analyzed the data, and wrote the paper.

Funding: This research was funded by Key R & D project of Shandong Province, China, grant number is 2017XCGC0605.

Acknowledgments: This work was supported by the Key Research and Development Plan Project of Shandong Province (No.2017XCGC0605).

Conflicts of Interest: The authors declare no conflict of interest.
