# A CONJECTURE CONCERNING INDEXES OF BEAUTY 

Maohua Le<br>Department of Mathematics<br>Zhanjiang Normal College<br>Zhanjiang, Guangdong<br>P. R. CHINA

Abstract. In this paper we prove that 64 is not an index of beauty.
Key words: divisor, index of beauty,

For any positive integer $n$, let $d(n)$ be the number of distinct divisors of $n$. It is a well known fact that if

$$
\begin{equation*}
n=p_{1}^{a_{1}} p_{2}^{a_{2}} \cdots p_{k}^{a_{1}} \tag{1}
\end{equation*}
$$

is the factorization of $n$, then we have

$$
\begin{equation*}
d(n)=\left(a_{1}+1\right)\left(a_{2}+1\right) \cdots\left(a_{k}+1\right) \tag{2}
\end{equation*}
$$

(see[1]). For a fixed positive integer $m$, if there exist a positive integer $n$ such that

$$
\begin{equation*}
m=\frac{n}{d(n)}, \tag{3}
\end{equation*}
$$

then in is called an index of beauty. Recently, Muthy 121 proposed the foliowing conjecture:

Conjecture Every positive integer is an index of beanit.
In this paper we give a counter-example for the above-mentioned conjecture. We prove the following result:

Theorem 64 is not an index of beauty.
Proof We now suppose that 64 is an index of beauty. Then there exist a positive integer $n$ such that

$$
\begin{equation*}
n=64 d(n) . \tag{4}
\end{equation*}
$$

We see from (4) that $n$ is even. Hence, $n$ has the factorization

$$
\begin{equation*}
n=2^{a_{0}} p_{1}^{a_{1}} \cdots p_{r}^{a_{1}} \tag{5}
\end{equation*}
$$

where $p_{1}, \cdots, p_{r}$ are odd primes with $p_{1}<\cdots<p_{r}, a_{0}$ is a positive integer with $a_{0} \geqslant 6, a_{1}, \cdots, a_{r}$ are positive integers. Let

$$
\begin{equation*}
b=a_{0}-6 \tag{6}
\end{equation*}
$$

By (4), (5) and (6), we get

$$
\begin{equation*}
2^{b} p_{1}^{a_{1}} \cdots p_{r}^{a_{r}}=(b+7)\left(a_{\mathrm{i}}+1\right) \cdots\left(a_{r}+1\right) . \tag{7}
\end{equation*}
$$

Since $p_{1}, \cdots, p_{r}$ are odd primes, we have

$$
\begin{equation*}
p_{i}^{a_{i}} \geq \frac{2}{3}\left(a_{1}+1\right), i=1, \cdots, r \tag{8}
\end{equation*}
$$

From (7) and (8), we get

$$
\begin{equation*}
b+7 \geq 2^{b}\left(\frac{3}{2}\right)^{r} \geq 2^{b-1} 3 . \tag{9}
\end{equation*}
$$

It implies that $b \leqslant 2$.
If $b=2$, thén from (7) we get $r=1$ and

$$
\begin{equation*}
4 p_{1}^{a_{1}}=9\left(a_{1}+1\right) \tag{10}
\end{equation*}
$$

whence we get $p_{1}=3, a_{1} \geqslant 2$ and

$$
\begin{equation*}
4 \cdot 3^{a_{1}-2}=a_{1}+1 . \tag{11}
\end{equation*}
$$

Since $4 \cdot 3^{a_{1}-2}>4\left(1+\left(a_{1}-2\right) \log 3\right)>4\left(a_{1}-1\right)>a_{1}+1$, (11) is impossible.
If $b=1$, then from (7) we get

$$
\begin{equation*}
p_{1}^{a_{1}} \cdots p_{r}^{a_{r}}=4\left(a_{1}+1\right) \cdots\left(a_{r}+1\right) . \tag{12}
\end{equation*}
$$

Since $p_{1}, \cdots, p_{r}$, are odd primes, (12) is impossible.
If $b=0$, then from (7) we get

$$
\begin{equation*}
p_{1}^{a_{1}} \cdots p_{r_{r}}^{a_{r}}=7\left(a_{1}+1\right) \cdots\left(a_{r}+1\right) . \tag{13}
\end{equation*}
$$

We see from (13) that $a_{1}+1, \cdots, a_{1}+1$ are odd. It implies that $a_{1}, \cdots, a_{r}$ are even. So we have $a_{i} \geqslant 2(i=1, \cdots, r)$ and

$$
\begin{equation*}
p_{i}^{u_{i}} \geq 3\left(a_{i}+1\right), i=1, \cdots, r . \tag{14}
\end{equation*}
$$

By (13) and (14), we get $r=1$. Further, by (13), we obtain $p_{1}=7$ and

$$
\begin{equation*}
7^{a_{1}-1}=a_{1}+1 . \tag{15}
\end{equation*}
$$

However, since $a_{1} \geqslant 2$, (15) is impossible. Thus, 64 is not an index of beauty. The theorem is proved.
