

# THE MONOTONY OF SMARANDACHE FUNCTIONS OF FIRST KIND

by Ion Bălăcenoiu

Department of Mathematics, University of Craiova  
Craiova (1100), Romania

Smarandache functions of first kind are defined in [1] thus:

$$S_n: N^* \rightarrow N^*, \quad S_1(k) = 1 \quad \text{and} \quad S_n(k) = \max_{1 \leq j \leq r} \{S_{p_j}(i_j k)\},$$

where  $n = p_1^{i_1} \cdot p_2^{i_2} \cdots p_r^{i_r}$  and  $S_{p_j}$  are functions defined in [4].

They  $\Sigma_1$ -standardise  $(N^*, +)$  in  $(N^*, \leq, +)$  in the sense that

$$\Sigma_1: \quad \max\{S_n(a), S_n(b)\} \leq S_n(a+b) \leq S_n(a) + S_n(b)$$

for every  $a, b \in N^*$  and  $\Sigma_2$ -standardise  $(N^*, +)$  in  $(N^*, \leq, \cdot)$  by

$$\Sigma_2: \quad \max\{S_n(a), S_n(b)\} \leq S_n(a+b) \leq S_n(a) \cdot S_n(b), \quad \text{for every } a, b \in N^*$$

In [2] it is proved that the functions  $S_n$  are increasing and the sequence  $\{S_{p^i}\}_{i \in N^*}$  is also increasing. It is also proved that if  $p, q$  are prime numbers, then

$$p \cdot i < q \Rightarrow S_{p^i} < S_{q^1} \quad \text{and} \quad i < q \Rightarrow S_i < S_q,$$

where  $i \in N^*$ .

It would be used in this paper the formula

$$S_p(k) = p(k - i_k), \quad \text{for same } i_k \text{ satisfying } 0 \leq i_k \leq \left\lfloor \frac{k-1}{p} \right\rfloor, \quad (\text{see [3]}) \quad (1)$$

**1. Proposition.** *Let  $p$  be a prime number and  $k_1, k_2 \in N^*$ . If  $k_1 < k_2$  then  $i_{k_1} \leq i_{k_2}$ , where  $i_{k_1}, i_{k_2}$  are defined by (1).*

*Proof.* It is known that  $S_p: N^* \rightarrow N^*$  and  $S_p(k) = pk$  for  $k \leq p$ . If  $S_p(k) = mp^\alpha$  with  $m, \alpha \in N^*$ ,  $(m, p) = 1$ , there exist  $\alpha$  consecutive numbers:

$$\begin{aligned} & n, n+1, \dots, n+\alpha-1 \quad \text{so that} \\ & k \in \{n, n+1, \dots, n+\alpha-1\} \quad \text{and} \\ & S_p(n) = S_p(n+1) = \dots = S_p(n+\alpha-1), \end{aligned}$$

this means that  $S_p$  is stationed the  $\alpha - 1$  steps ( $k \rightarrow k + 1$ ).

If  $k_1 < k_2$  and  $S_p(k_1) = S_p(k_2)$ , because  $S_p(k_1) = p(k_1 - ik_1)$ ,  $S_p(k_2) = p(k_2 - ik_2)$  it results  $i_{k_1} < i_{k_2}$ .

If  $k_1 < k_2$  and  $S_p(k_1) < S_p(k_2)$ , it is easy to see that we can write:

$$i_{k_1} = \beta_1 + \sum_{\alpha} (\alpha - 1) \quad \text{where} \quad \beta_1 = 0 \text{ for } S_p(k_1) \neq mp^\alpha, \quad \text{if } S_p(k_1) = mp^\alpha$$

$$mp^\alpha < S_p(k_1)$$

then  $\beta_1 \in \{0, 1, 2, \dots, \alpha - 1\}$   
and

$$i_{k_2} = \beta_2 + \sum_{\alpha} (\alpha - 1) \quad \text{where} \quad \beta_2 = 0 \text{ for } S_p(k_2) \neq mp^\alpha, \quad \text{if } S_p(k_2) = mp^\alpha \text{ then}$$

$$mp^\alpha < S_p(k_2)$$

$\beta_2 \in \{0, 1, 2, \dots, \alpha - 1\}$ .

Now is obviously that  $k_1 < k_2$  and  $S_p(k_1) < S_p(k_2) \Rightarrow i_{k_1} \leq i_{k_2}$ . We note that, for  $k_1 < k_2$ ,  $i_{k_1} = i_{k_2}$  iff  $S_p(k_1) < S_p(k_2)$  and  $\{mp^\alpha \mid \alpha > 1 \text{ and } mp^\alpha \leq S_p(k_1)\} = \{mp^\alpha \mid \alpha > 1 \text{ and } mp^\alpha < S_p(k_2)\}$

**2. Proposition.** *If  $p$  is a prime number and  $p \geq 5$ , then  $S_p > S_{p-1}$  and  $S_p > S_{p+1}$ .*

*Proof.* Because  $p - 1 < p$  it results that  $S_{p-1} < S_p$ . Of course  $p + 1$  is even and so:

(i) if  $p + 1 = 2^i$ , then  $i > 2$  and because  $2i < 2^i - 1 = p$  we have  $S_{p+1} < S_p$ .

(ii) if  $p + 1 \neq 2^i$ , let  $p + 1 = p_1^{i_1} \cdot p_2^{i_2} \cdots p_r^{i_r}$ , then  $S_{p+1}(k) = \max_{1 \leq j \leq r} \{S_{p_j^{i_j}}(k)\} = S_{p_m^{i_m}}(k) = S_{p_m}(i_m \cdot k)$ .

Because  $p_m \cdot i_m \leq p_m^{i_m} \leq \frac{p+1}{2} < p$  it results that  $S_{p_m^{i_m}}(k) < S_p(k)$  for  $k \in \mathbb{N}^*$ , so that  $S_{p+1} < S_p$ .

**3. Proposition.** *Let  $p, q$  be prime numbers and the sequences of functions*

$$\{S_{p^i}\}_{i \in \mathbb{N}^*}, \quad \{S_{q^j}\}_{j \in \mathbb{N}^*}$$

*If  $p < q$  and  $i \leq j$ , then  $S_{p^i} < S_{q^j}$ .*

*Proof.* Evidently, if  $p < q$  and  $i \leq j$ , then for every  $k \in \mathbb{N}^*$

$$S_{p^i}(k) \leq S_{p^j}(k) < S_{q^j}(k)$$

so,

$$S_{p^i} < S_{q^j}$$

**4. Definition.** *Let  $p, q$  be prime numbers. We consider a function  $S_{p^i}$ , a sequence of functions  $\{S_{p^i}\}_{i \in \mathbb{N}^*}$ , and we note:*

$$i_{(j)} = \max_i \{i \mid S_{p^i} < S_{q^j}\}$$

$$i^{(j)} = \min \{i \mid S_{q'} < S_{p'}\},$$

then  $\{k \in N \mid i_{(j)} < k < i^{(j)}\} = \Delta_{p'(q')} = \Delta_{i(j)}$  defines the interference zone of the function  $S_{q'}$  with the sequence  $\{S_{p'}\}_{i \in N^*}$ .

**5. Remarque.**

a) If  $S_{q'} < S_{p'}$  for  $i \in N^*$ , then now exists  $i^{(j)}$  and  $i^{(j)} = 1$ , and we say that  $S_{q'}$  is separately of the sequence of functions  $\{S_{p'}\}_{i \in N^*}$ .

b) If there exist  $k \in N^*$  so that  $S_{p'} < S_{q'} < S_{p'+1}$ , then  $\Delta_{p'(q')} = \emptyset$  and say that the function  $S_{q'}$  does not interfere with the sequence of functions  $\{S_{p'}\}_{i \in N^*}$ .

**6. Definition.** The sequence  $\{x_n\}_{n \in N^*}$  is generally increasing if

$$\forall n \in N^* \exists m_0 \in N^* \text{ so that } x_m \geq x_n \text{ for } m \geq m_0.$$

**7. Remarque.** If the sequence  $\{x_n\}_{n \in N^*}$  with  $x_n \geq 0$  is generally increasing and bounded, then every subsequence is generally increasing and bounded.

**8. Proposition.** The sequence  $\{S_n(k)\}_{n \in N^*}$ , where  $k \in N^*$ , is in generally increasing and bounded.

*Proof.* Because  $S_n(k) = S_{n,k}(1)$ , it results that  $\{S_n(k)\}_{n \in N^*}$  is a subsequence of  $\{S_m(1)\}_{m \in N^*}$ .

The sequence  $\{S_m(1)\}_{m \in N^*}$  is generally increasing and bounded because:

$$\forall m \in N^* \exists t_0 = m! \text{ so that } \forall t \geq t_0 S_t(1) \geq S_{t_0}(1) = m \geq S_m(1).$$

From the remarque 7 it results that the sequence  $\{S_n(k)\}_{n \in N^*}$  is generally increasing bounded.

**9. Proposition.** The sequence of functions  $\{S_n\}_{n \in N^*}$  is generally increasing bounded.

*Proof.* Obviously, the zone of interference of the function  $S_m$  with  $\{S_n\}_{n \in N^*}$  is the set

$$\Delta_{n(m)} = \{k \in N^* \mid n_{(m)} < k < n^{(m)}\} \text{ where}$$

$$n_{(m)} = \max \{n \in N^* \mid S_n < S_m\}$$

$$n^{(m)} = \min \{n \in N^* \mid S_m < S_n\}.$$

The interference zone  $\Delta_{n(m)}$  is nonempty because  $S_m \in \Delta_{n(m)}$  and finite for  $S_1 \leq S_m \leq S_p$ , where  $p$  is one prime number greater than  $m$ .

Because  $\{S_n(1)\}$  is generally increasing it results:

$$\forall m \in \mathbb{N}^* \exists t_0 \in \mathbb{N}^* \text{ so that } S_r(1) \geq S_m(1) \text{ for } \forall t \geq t_0.$$

For  $r_0 = t_0 + n^{(m)}$  we have

$$S_r \geq S_m \geq S_m(1) \text{ for } \forall r \geq r_0,$$

so that  $\{S_n\}_{n \in \mathbb{N}^*}$  is generally increasing bounded.

### 10. Remarque.

a) For  $n = p_1^{i_1} \cdot p_2^{i_2} \cdots p_r^{i_r}$  are possible the following cases:

1)  $\exists k \in \{1, 2, \dots, r\}$  so that

$$S_{p_j} \leq S_{p_k} \text{ for } j \in \{1, 2, \dots, r\},$$

then  $S_n = S_{p_k^{i_k}}$  and  $p_k^{i_k}$  is named the dominant factor for  $n$ .

2)  $\exists k_1, k_2, \dots, k_m \in \{1, 2, \dots, r\}$  so that :

$$\forall t \in \overline{1, m} \quad \exists q_t \in \mathbb{N}^* \text{ so that } S_n(q_t) = S_{p_{k_t}^{i_{k_t}}}(q_t) \text{ and}$$

$$\forall l \in \mathbb{N}^* \quad S_n(l) = \max_{1 \leq t \leq m} \left\{ S_{p_{k_t}^{i_{k_t}}}(l) \right\}.$$

We shall name  $\{p_{k_t}^{i_{k_t}} \mid t \in \overline{1, m}\}$  the active factors, the others would be name passive factors for  $n$ .

b) We consider

$$N_{p_1 p_2} = \{n = p_1^{i_1} \cdot p_2^{i_2} \mid i_1, i_2 \in \mathbb{N}^*\}, \text{ where } p_1 < p_2 \text{ are prime numbers.}$$

For  $n \in N_{p_1 p_2}$  appear the following situations:

1)  $i_1 \in (0, i_1^{(i_2)}]$ , this means that  $p_1^{i_1}$  is a pasive factor and  $p_2^{i_2}$  is an active factor.

2)  $i_1 \in (i_1^{(i_2)}, i_1^{(i_2)})$  this means that  $p_1^{i_1}$  and  $p_2^{i_2}$  are active factors.

3)  $i_1 \in [i_1^{(i_2)}, \infty)$  this means that  $p_1^{i_1}$  is a active factor and  $p_2^{i_2}$  is a pasive factor.

For  $p_1 < p_2$  the repartition of exponents is represently in following scheme:

For numbers of type 2)  $i_1 \in (i_{1(i_2)}, i_1^{(i_2)})$  and  $i_2 \in (i_{2(i_1)}, i_2^{(i_1)})$

c) I consider that

$$N_{p_1 p_2 p_3} = \{n = p_1^{i_1} \cdot p_2^{i_2} \cdot p_3^{i_3} \mid i_1, i_2, i_3 \in \mathbb{N}^*\},$$

where  $p_1 < p_2 < p_3$  are prime numbers.

Exist the following situations:

1)  $n \in N^{p_j^{i_j}}$ ,  $j = 1, 2, 3$  this means that  $p_j^{i_j}$  is active factor.

2)  $n \in N^{p_j^{i_j} p_k^{i_k}}$ ,  $j \neq k$ ;  $j, k \in \{1, 2, 3\}$ , this means that  $p_j^{i_j}, p_k^{i_k}$  are active factors.

3)  $n \in N^{p_1^{i_1} p_2^{i_2} p_3^{i_3}}$ , this means that  $p_1^{i_1}, p_2^{i_2}, p_3^{i_3}$  are active factors.  $N^{p_1 p_2 p_3}$  is named the S-active cone for  $N_{p_1 p_2 p_3}$ .

Obviously

$$N^{p_1 p_2 p_3} = \{n = p_1^{i_1} p_2^{i_2} p_3^{i_3} \mid i_1, i_2, i_3 \in \mathbb{N}^* \text{ and } i_k \in (i_{k(i_j)}, i_k^{(i_j)}) \text{ where } j \neq k; j, k \in \{1, 2, 3\}\}.$$

The repartition of exponents is represented in the following scheme:

For  $p_1 < p_2$  the repartition of exponents is represently in following scheme:

For numbers of type 2)  $i_1 \in (i_{1(i_2)}, i_1^{(i_2)})$  and  $i_2 \in (i_{2(i_1)}, i_2^{(i_1)})$

c) I consider that

$$N_{p_1 p_2 p_3} = \{n = p_1^{i_1} \cdot p_2^{i_2} \cdot p_3^{i_3} \mid i_1, i_2, i_3 \in \mathbb{N}^*\},$$

where  $p_1 < p_2 < p_3$  are prime numbers.

Exist the following situations:

- 1)  $n \in N^{p_j^{i_j}}$ ,  $j = 1, 2, 3$  this means that  $p_j^{i_j}$  is active factor.
- 2)  $n \in N^{p_j^{i_j} p_k^{i_k}}$ ,  $j \neq k$ ;  $j, k \in \{1, 2, 3\}$ , this means that  $p_j^{i_j}, p_k^{i_k}$  are active factors.
- 3)  $n \in N^{p_1^{i_1} p_2^{i_2} p_3^{i_3}}$ , this means that  $p_1^{i_1}, p_2^{i_2}, p_3^{i_3}$  are active factors.  $N^{p_1 p_2 p_3}$  is named the S-active cone for  $N_{p_1 p_2 p_3}$ .

Obviously

$$N^{p_1 p_2 p_3} = \{n = p_1^{i_1} p_2^{i_2} p_3^{i_3} \mid i_1, i_2, i_3 \in \mathbb{N}^* \text{ and } i_k \in (i_{k(i_j)}, i_k^{(i_j)}) \text{ where } j \neq k; j, k \in \{1, 2, 3\}\}.$$

The repartition of exponents is represented in the following scheme:

d) Generally, I consider  $N_{p_1 p_2 \dots p_r} = \{n = p_1^{i_1} \cdot p_2^{i_2} \cdot \dots \cdot p_r^{i_r} \mid i_1, i_2, \dots, i_r \in \mathbb{N}^*\}$ , where  $p_1 < p_2 < \dots < p_r$  are prime numbers.

On  $N_{p_1 p_2 \dots p_r}$  exist the following relation of equivalence:

$$n \rho m \Leftrightarrow n \text{ and } m \text{ have the same active factors.}$$

This have the following clases:

-  $N^{p_{j_1}^{i_{j_1}}}$ , where  $j_1 \in \{1, 2, \dots, r\}$ .

$n \in N^{p_{j_1}^{i_{j_1}}} \Leftrightarrow n$  hase only  $p_{j_1}^{i_{j_1}}$  active factor

-  $N^{p_{j_1}^{i_{j_1}} p_{j_2}^{i_{j_2}}}$ , where  $j_1 \neq j_2$  and  $j_1, j_2 \in \{1, 2, \dots, r\}$ .

$n \in N^{p_{j_1}^{i_{j_1}} p_{j_2}^{i_{j_2}}} \Leftrightarrow n$  has only  $p_{j_1}^{i_{j_1}}, p_{j_2}^{i_{j_2}}$  active factors.

.....

$N^{p_1^{i_1} p_2^{i_2} \dots p_r^{i_r}}$  wich is named S-active cone.

$$N^{p_1^{i_1} p_2^{i_2} \dots p_r^{i_r}} = \{n \in N_{p_1 p_2 \dots p_r} \mid n \text{ has } p_1^{i_1}, p_2^{i_2}, \dots, p_r^{i_r} \text{ active factors}\}.$$

Obviously, if  $n \in N^{p_1^{i_1} p_2^{i_2} \dots p_r^{i_r}}$ , then  $i_k \in (i_{k(i_j)}, i_k^{(i_j)})$  with  $k \neq j$  and  $k, j \in \{1, 2, \dots, r\}$ .
